Date 8 Apr. 2014. Black Sugarloaf, Birralee (Thismia gully).

Habitat: Closed wet Eucalypt forest.

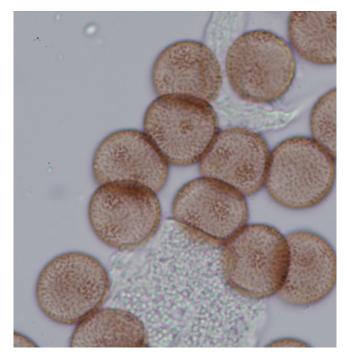

Substrate: Decayed (soft, spongy) stag of fallen dead

Eucalyptus obliqua.

Description: small groups of crowded and heaped stalked sporangia, appearing sessile but some stalked. **Sporotheca** laterally compressed or misshapen by mutual pressure, stalked sporotheca subulate at base. **Stalk** subulate, slightly wrinkled, brown at base, lighter at apex, 0.4 mm long. **Hypothallus** inconspicuous. **Peridium** encrusted with green lime, some crystalline. **Capillitium** fine yellow lime. **Spores**: dark brown in mass, lighter brown by transmitted light, warted with patches of darker warts, $8.5-9.5~\mu m$.

Notes: Keys out to *P. virescens* except for the presence of stalks in some sporangia.

Physarum cf. virescens Ditmar

Date 21 Jan. 2015 Same location and substrate as #0220 above. Most sporangia on spongy part of wood with toothed resupinate fungus. **Description**: Clustered and scattered mostly sessile (some stalked) sporangia, of very variable shape, 0.6 x 0.4 mm diameter. **Stalk** extension of hypothallus, brown. **Hypothallus** membranous, brown. **Peridium** crystalline layer encrusted with green lime. **Capillitium** sparse small yellow lime nodes. **Spores**: dark brown in mass, lighter brown by transmitted

Spores: dark brown in mass, lighter brown by transmitted light, warted with patches of darker warts, $7.5–8.5 \mu m$. **Notes** Only two collections of this species, both from the same substrate.
